Pressure Injuries

These guidelines have been developed for health professionals caring for clients with or at risk of pressure injuries.

Assessment, management and prevention of pressure injury should be undertaken by health professionals with expertise in the area.

For this summary, all recommendations have had their levels of evidence classified using the National Health and Medical Research Council levels of evidence, as follows:

Level I	Evidence from a systematic review or meta-analysis of at least two level II studies
Level II	Evidence from a well designed randomised controlled trial (for interventions), or a prospective cohort study (for prognostic studies)
Level III	Evidence from non-randomised studies with some control or comparison group (pseudorandomised controlled trial; non-randomised experimental trial, cohort study, case-control study, time series studies with a control group; historical control study, retrospective cohort study)
Level IV	Evidence from studies with no control or comparison group

An additional rating of Expert Opinion (EO) has been added, for guideline recommendations which are consensus statements provided by a National or International Panel of experts in the area.

This is a summary of guidelines from the following sources, which should be accessed for further details as required:

Assessment

- 1. All clients should be assessed for their risk of developing pressure injuries on admission and following any change in health status.^{1, 2} The resulting risk status and risk factors should be documented regularly.³

 Include a skin assessment¹; (III) medical/surgical history¹; (EO) and a pressure injury risk assessment tool.^{1, 2, 4, 5} (IIII)

 There is little evidence supporting the effectiveness of any one risk
- Assessment should be carried out by staff with training and expertise in the assessment of risk factors and pressure injuries^{3, 6}

assessment tool over another1

- 3. Risk factors include:
 - Immobility or reduced physical mobility^{3, 6, 7} (III)
 - Loss of sensation^{3, 6} (III)
 - Impaired cognitive state or level of consciousness⁶ (III)
 - Urinary or faecal incontinence³ (III)
 - Poor nutrition or recent weight loss^{3, 6, 7} (III)
 - Dry skin⁷ (III)
- Individuals found to be at risk of developing pressure injuries should have their skin assessed daily for signs

- Acute or severe illness3,6

of impaired skin integrity^{1,8}

Regularly assess and monitor
wound characteristics (i.e. location,
dimensions, stage, exudate
characteristics, signs of infection,
wound bed characteristics, surrounding
skin, undermining or tracking, odour),
and progress in healing, including use
of a validated pressure injury healing
assessment scale¹ (III)

6. All clients with pressure injuries should be regularly assessed for presence of pain^{1, 5} (IV) using a validated pain assessment tool^{1, 5} (III) and a pain management plan developed¹ (EO)

Management

(II)

(III)

(III)

(III)

- The pressure injury stage should be documented using an accepted classification system, e.g. the NPUAP/EPUAP 2009 pressure injury classification system¹ (EO)
- Pressure-relieving surfaces and strategies (e.g. mobilising, regular repositioning) should be in place 24 hours/day for all individuals with pressure injuries^{6,7,9} (IV)
- 9. A high specification reactive (constant low pressure) or active (alternating pressure) support surface should be used in clients with pressure injuries¹ (1)
- If there is no progress in healing, or a stage 3 – 4 injury is present (or unstageable or deep tissue injuries), an alternating pressure, low-air-loss, continuous low pressure system or airfluidised bed should be used^{7,9} (1)
- A static support surface may be appropriate for clients who can move freely and where there is no 'bottoming out'², ⁹; (I) for clients who cannot move freely, or who 'bottom out', a dynamic support surface may be appropriate⁹ (I)
- 12. Avoid positioning individuals directly on pressure injuries or bony prominences¹ (III)

13. Limit the amount of time with the of bed elevated ^{3,9}
14. The initial plant of he imigrated with

e head

(III)

(IV)

(II)

(1)

(III)

(II)

(III)

- 14. The injury should be irrigated with a neutral, non-irritating, non-toxic solution, and cleansing undertaken with minimal chemical or mechanical trauma9
- 15. Removal of necrotic and devitalised tissue should be undertaken through mechanical, sharp, autolytic or biological debridement9
- 16. Dressings should:
 - Maintain a moist wound-healing environment1,9
 - Manage wound exudate and protect peri-ulcer skin^{1,9} (1)
 - Remain in place and minimise shear, friction, skin irritation and pressure9 (II)
- 17. There is insufficient evidence to indicate:
 - Whether any specific dressing is more effective in healing pressure injuries¹
 - Whether antimicrobials are effective in treating pressure injuries7 (1)

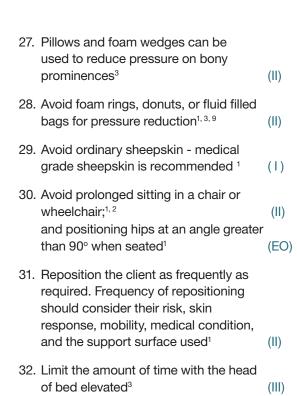

However, hydrocolloid dressings are generally more cost-effective than moist gauze1 (III)

- 18. The following interventions may promote healing in pressure injuries when used in combination with regular care:
 - Topical negative pressure therapy, in stage 3-4 pressure injuries¹
 - Electrotherapy, in stage 2-4 injuries1
 - Pulsed electromagnetic therapy, in stage 2-4 injuries1
 - Ultraviolet light C therapy, in stage 2-4 injuries1 (IV)

- 19. There is currently insufficient evidence to recommend:
 - Hyperbaric oxygen therapy¹ (1)
 - Infrared therapy1 (EO) - Laser therapy1 (EO)
 - Therapeutic ultrasound therapy¹ (I)
- 20. Provide high protein oral nutritional supplements in addition to a regular diet for clients with a pressure injury, including arginine supplements in people with a stage 2 or greater pressure injury1 (II)

Prevention

- 21. Formal documented policies and procedures should be in place to guide prevention plans for pressure injuries, including identification of areas and groups at risk³ (III)
- 22. Individuals found to be at risk of developing pressure injuries should have a preventative management plan in place1 (II)
- 23. A multidisciplinary team of health care professionals should evaluate preventative pressure injury care strategies at least quarterly3 (III)
- 24. High specification reactive support foam mattresses should be used rather than standard mattresses in individuals found as being at risk of developing a pressure injury.1 Active support mattresses could be used as an alternative in these clients1 (1)
- 25. Heels should be completely off loaded in all positions for at-risk individuals⁵ (IV)
- 26. Avoid positioning individuals directly on bony prominences1 (EO)

and maintain head of bed at/or below 30° or at the lowest degree of

33. Employ correct lifting and manual

34. Protect skin exposed to friction¹

handling techniques, including use of lift sheets or devices to transfer clients^{1, 3}
